It’s recommended but optional.
To enhance your email deliverability, you can enable and configure DKIM for your domain. Follow these straightforward steps to enable and set up DKIM:

1. Go to the “Domains” section.
2. Select your domain and click on the right 3 dots to open the menu, then click on “View DNS”.
3. Check if the DKIM feature is already enabled for your email accounts, If not enable it by clicking on the right sidebar “**Enable DKIM**“.Note: If it is displayed as ‘Disable DKIM,’ as shown in the photo, it indicates that DKIM is already enabled, and you can proceed to the next step.
4. A new DNS pop-up will appear.
5. Copy the DKIM key from the DNS management within the Advanced Mail Manager, which was previously generated for you and follows the following format:
   Hostname: dkim selector
   Value: “v=DKIM1; k=rsa; p=MIIBIjANBgkqhkiG9w0BAQEFAAOCAQ8AMIIBCgKCAQEA76dPAW7hNPUMjODOFlQvLQSAkQ37thRpU3uTGqmcmW4ClxjVIN0goYVk01eocqO66W6gz/yDWYxW+FAbJlQ/KrAAq1ZpQ.....” **Replace this with the actual value from your DNS management page**.
   Type: TXT
   TTL: It’s recommended to set it to 300 or lower if possible.

6. **Create** the above record to your domain’s DNS management(**Your domain provider**), just as you did with the SPF and MX records.

Congratulations! You’ve successfully enabled and configured the DKIM record for your domain.

We suggest verifying the validity and visibility of these records using this online tool: **MSG25 DKIM Lookup.**
